the Proposal Process (in general)

- Two proposal calls per year
- Deadline is real!
- Technical Reviews (by facility scientists) – feasibility, safety...
- Peer Review by Scientific Experts
 - Classification is done by subject or technique
 - At least 2 reviewers per proposal
 - Panel meetings at facilities (or by Skype)
 - Time recommended
- Final balance (eg. national funding)
- Letters sent out to PI's

Things to keep in mind...

Scientific reviewers are not always experts in your specialty since science at the facilities is so diverse.

So, don't assume they know everything.

Most reviewers spend 10-15 minutes per proposal!

Many will not have time to read through the references!

So, you must get all **relevant information** in the proposal.

Make your **point, clearly** and **succinctly**.

Proposal Ingredients (Part I)

- User/participant information
- Title and abstract
- Sample description
- Sample environment requirements
- Instrument specs requested and time
- Publications, student thesis, scientific area, grants, submission status, safety...

Previous results

Aim of proposed work

Proposed experiments

Here is our experimental plan:

- 1) Instrument: KWS1 with rheo-meter (Anton Paar)
- 2) Shear-rate: 0 s^{-1} , 0.1 s^{-1} , 1 s^{-1} , 3 s^{-1} , 5 s^{-1} , 7 s^{-1} , 10 s^{-1} , 60 s^{-1} , 100 s^{-1} , 1000 s^{-1}
- 3) The measured spatial domain: $Q = 0.003 \text{ Å}^{-1}$ to 0.3 Å^{-1}
- 4) Sample: (i) D_2O / 3-methylpyridine / NaBPh_4
(ii) D_2O / C_{14}E_5
- 5) Temperature: 298 K

We assume that one measurement takes 45 minutes (15 minutes at high-Q and 45 minutes at low-Q region). Then, the total measurement time is estimated as

$$0.75 \text{ (hours)} \times 10 \text{ (shear rate)} \times 2 \text{ (samples)} \times 1 \text{ (temperature)} = 15 \text{ (hours)}.$$

Additionally, we need 8 hours for setting rheo-meter and changing the detector length. Therefore, we request 1 days beam-time.

Your publication record (give references to papers published in the last two years arising from experiments at FRM II instruments)

There is no paper arising from experiments at FRM II instruments.

2-page Case including references and figures/tables

Changes in lipid dynamics induced by melittin absorption on membrane surfaces

The rise of infectious bacterial strains resistant to current antibiotic treatments is a growing concern universally. This has spurred an intensified interest both in the discovery and understanding of naturally occurring anti-microbial agents and the molecular mechanism by which they function. Most anti-microbial compounds associate with the cellular membrane and disrupt the delicate electro-chemical balance required for bacterial cellular life. One such naturally occurring molecule is melittin (MLT), found in the venom of honeybees. MLT poses many characteristics shared among known anti-microbial peptides. It is a single domain α -helix with a strong amphipathic quality (Fig. 1a). Structural studies from X-ray diffraction experiments [1] show partitioning into the lipid membrane of cells: intercalating with the headgroup region (Fig. 1b). Significant perturbations to the lipid chains are also observed: a thinning of the hydrocarbon region as well as a broadening of the terminal methyl distribution suggest an increase in chain disorder due to MLT's presence. At higher concentrations, MLT fully penetrates the membrane as self-assembled helical bundles that form large pores in the membrane, leading to cell death.

Detailed structural data from diffraction experiments has helped elucidate the function of MLT. However the mechanism for biological activity stems from the dynamics. We propose to use quasielastic neutron scattering (QENS) to characterize the changes in mobility of a model dioleoylphosphatidylcholine (DOPC) phospholipid membrane, in the presence of MLT. The protein:lipid system will be divided into three major components, the phospholipid headgroups, the lipid hydrocarbon tails and the MLT itself. Selective deuteration will allow us to follow the mobility of each of the three components separately. Regions of lipid that interact with MLT the most will be identified by comparison of dynamical changes with the pure DOPC bilayer measurements. Furthermore a study combining molecular dynamic (MD) simulations with neutron results on a similar system [2] suggests that regulating the mobility of phospholipid headgroups controls melting transitions. Measuring the effect on the membrane T_m provides another method for probing the balance between headgroup and chain interactions with MLT.

Previous QENS measurements of ordered lipid systems have used a combination of several dynamic models to describe motions in the ps to ns range of accessible time scales [1,3-4]. Given the sub ns dynamic range of the IRIS backscattering instrument our experiments will primarily be sensitive to methyl rotations, dihedral isomerization and localized diffusion (Fig. 2a). Despite the use of selective deuteration, the dynamical processes are still complex and may prove difficult to dissect into their individual contributions. Therefore, we will use an experimentally validated MD simulation [5] to provide a powerful method for aiding in the interpretation of QENS data, since there is total overlap in time and length scales accessed by both methods. Preliminary analysis of a DOPC/MLT simulation already provides some insights into potential perturbation in lipid dynamics caused by the peptide. Fig. 2b shows a snapshot of the simulation in which lipids within the vicinity of the protein are either highly kinked or extended. Furthermore the less mobile headgroups adjust their packing behavior around MLT. The results already suggest a possible framework for interpreting QENS data for this system.

We propose to perform experiments on the following samples:

- (1) Fully hydrogenated DOPC [hh-DOPC]
- (2) Fully hydrogenated DOPC with melittin [hh-DOPC+h-melittin]
- (3) Hydrogenated head-group DOPC [hd-DOPC]
- (4) Hydrogenated head-group DOPC with melittin [hd-DOPC+h-melittin]

The experiments proposed are presented in turn below:

(a) Elastic window scans (10-350K): elastic scans will give us a number of preliminary results. A comparison of the scans of the non-labeled lipid with and without MLT (samples 1,2), will show changes in T_m and in the dynamic regimes within the timescale of the IRIS spectrometer. Comparing head labeled with fully hydrogenated (signal dominated by tail protons) DOPC will indicate if the gel-to-fluid transition is characteristic to a specific part of the lipid (samples 1,3). Addition of the MLT to the labeled DOPC will show any differences in mobility in the presence of MLT that are specific to the individual components of the lipid (samples 2,4). Finally, mean-square displacement data for all samples will reveal changes in the mobility of all three components in the system (all samples). Elastic scans will require 3 days.

(b) Dynamic runs: we propose to measure the dynamics of each of samples 3-6 at two temperatures, below and above T_m . The measurements will allow analysis of the mobility of the DOPC head and tail groups quantitatively (samples 1,3), allowing for precise assessment of their response to the addition of MLT (samples 2,4). These experiments require 4 days (assuming 12hr per temperature run based on sample quantities).

The samples will consist of multilayers of DOPC and DOPC/MLT mixtures containing 1.5 mol % MLT per mol DOPC, plated onto a series of silicon wafers. Around 15 wafers are stacked in an aluminium slab-shaped cell with the face area of the same dimensions as the neutron beam. Such a cell has already been used for experiments on the backscattering spectrometer at the NIST Center for Neutron Research. The cell is contained in a humidity chamber and the samples are kept at 66 % r.h. with a NaNO_2 solution in D_2O . Use of D_2O allows minimization of incoherent scattering from the buffer and also from the exchangeable protons in the MLT. The concentration of MLT and the humidity is chosen to match the MD simulations and diffraction experiments.

We propose to use the IRIS spectrometer with the PG002 configuration at a resolution of 8.8 μeV (HWHM) and an energy range of 1.0 meV, giving us access to timescales between ca. 0.5-100 ps. The Q-range accessible is 0.3- 1.8 inv. Ang. These distances and times are directly comparable to the MD simulations. For the completion of the proposed work we are requesting a total of 7 days.

We note that this is a resubmission of RB 0720585 which was awarded 7days. Since then we have been trying to synthesize MLT and encountered some difficulties, thus we have not used our beamtime and we thought it would be better to resubmit. We now have a successful route for expressing MLT and will be ready to perform the experiment.

Figure 1: (a) The amphipathic MLT monomer is shown with polar residues in green, basic residues in blue and non-polar residues in grey. (b) X-ray scattering length density profiles show MLT partitioning into the lipid headgroup region of a dioleoylphosphatidylcholine (DOPC) bilayer [1].

Figure 2: (a) A schematic of accessible motions on the sub ns time scale. Straight arrows represent localized mobility and circular arrows represent dihedral isomerization or terminal methyl rotation. (b) Snapshot of a DOPC/MLT MD simulation. Perturbation to lipid tail conformation and packing defects in lipid headgroups are evident.

Do's and Don't's'

- ✓ Use all space allocated
- ✓ Add **readable** figures/graphs
- ✓ Justify need for neutrons
- ✓ Add references
- ✓ Check before submission
- ✗ Use miniture font
- ✗ Include if they do not add to proposal
- ✗ Use generic arguments
- ✗ Expect reviewer to read
- ✗ Make silly mistakes

Proposal Submission

- Online
- Read guidelines for given facility system
- Follow instructions carefully
- Meet the deadline (don't play tricks!)

INSTITUT MAX VON LAUE - PAUL LANGEVIN (ILL)

Guidelines for the scientific background and detailed description of the proposed experiment

(For electronic proposal submission only)

Please remove this first page before creating your post-script file

The two pages of this form are to be filled in by all users or groups of users who apply for beamtime for experiments at the ILL via the Internet. Please print pages two and three of this document into a postscript file and attach it to your proposal on the Electronic Proposal System. This two-page description will be reduced by the system to a one-page, A4 format in black & white, and will be attached to your web proposal.

When preparing your description, please follow the instructions below:

- Give a brief statement of the **background** and the general importance of the research.
- Give a clear account of the **aims of the proposed experiment** and a detailed description of the experiment; keep in mind that not all of the subcommittee members are experts in the field.

Proposal Review Process

- Panel review
 - By technique or by science area
 - At least 2 reviewers per proposal
 - Panel review meeting at the facility

Proposal Review Process

- Proposal is given a rating (e.g. 1 to 5 in steps of 0.5)
- Typical marking definitions (NCNR, NIST)
 - 5 = E = Excellent proposal. Experiment must be carried out. Highest priority for beamtime.
 - 4 = VG = Very good proposal. Experiment is highly deserving of beamtime. No reason to deny beamtime except under conditions of unusually high demand.
 - 3 = G = Good proposal. May receive beamtime under normal circumstances, but may not, depending on demand.
 - 2 = F = Fair proposal. While scientific merit does not appear to be exceptionally high, the experiment may receive beamtime if its is available, but will probably not receive time
 - 1 = P = Poor proposal. Scientific merit not convincingly documented. Beamtime should not be allocated to the proposal.

Examples of Reviewers Comments

Rating: **Excellent**

Comments: This is a **very well described proposal, system is well pre-characterised**. The **use of neutrons is justified** to look at the Q-dependence and discern the origins of the changes induced by confinement in a strongly H-bonded system. There is **clear justification about the need to perform a concentration dependence study and compare with their previous studies** on QENS on the bulk samples.

Rating: **Very Good**

Comments: The importance of understanding the effect of nanoparticles in polymer nanocomposites is clear for a number of applications. This proposal **aims to differentiate** between the roles of chemi- and physi-sorption in the dynamics of the polymer. Polymer A is the chosen polymer whose **dynamics** in the melt clearly **falls within the NSE window based on their earlier measurements**. **The authors mention two ways of differentiating** this: with temperature and by replacing the –OH terminal groups by –CH₃s. It seems to me that the latter would provide a much more cleaner difference, and hence there is **no need to do the different temperatures. This would also reduce their beamtime** to around 10 days rather than 15. All in all I believe this proposal is well thought out and presented, very systematic and the data will be analyzed in terms of well-established models.

Rating: **Average**

Comments: The **scientific context** of the proposal is **nicely set out** and the **main aim of the experiment as well**. I recognise the **difficulty of perdeuterating the protein** as well as the substrate, but it is **unclear why the choice of 6 samples**. For example, why do the authors need to measure samples (3) and (6) – **it is not clear to me what additional information they will learn**. In particular I think that it will be **hard to separate out the dynamics of the two individual components** in sample (6), given that there will be two collective responses. For samples (4) and (5) it would have been helpful to have added what the relevant incoherent scattering contributions are. In addition, the authors point out that samples (2-4) and (6) will be measured only at one temperature of 300K and samples (1) to (5) at many. **This needs to be explained**.

Examples of Reviewers Comments

Rating: **Poor**

Comments: I'm afraid that I found this proposal very hard to review: it was **difficult to read and understand it**, the **scientific case was not properly justified**, I couldn't understand **why this was not a 'continuation' proposal** since the authors have already measured two crystallinities before - assuming that this is what they are asking to do in this current proposal, the **reason for multi Ei was not justified**. From a more scientific point of view, the **previous data has not really been explained** except to say that at higher crystallinity there is stronger phonon intensity. I can see how there seems to be a change in the Boson to QENS at around 230K but I don't understand that "this suggests that the transition of side chains might be below 230K." Finally **I would suggest that if you want to look at the QENS of the side chains below 230K you try a higher resolution machine** so you can move away from the Boson peak intensity - try DNA at J-PARC. **All in all I think that although the experiment is do-able it is not clear what the authors want to learn and how they will elucidate this.**

Rating: **Poor**

Comments: This proposal **makes very little experimental sense**. 1) they propose to do elastic scans on a chopper machine. This is the **wrong instrument** in my opinion. 2) A **clear plagiarism and non-referencing** from Mr Y's original work refers to the wrong spectrometer for performing the measurement! **They do not even know how the instrument works, never mind being capable of analyzing the data** after even if they get help from the local scientists. I have no confidence in this group being able to successfully use this time if allocated.

Success ...

... depends on many factors:

- Quality of proposal
- Days available
- Oversubscription
- Committee's feeling about high risk-high reward proposal versus unexciting but definite publication
- Mood, tiredness...
- Country balances
- ...

Any questions?!

Neutron Proposal Exercise 1

- You will be given a proposal and asked to review it
- One of you will be the 'Rapporteur', others reviewers
- Rate as
 - 1 – poor
 - 2 – average
 - 3 – good
 - 4 - excellent
- Give some justifications for your score
- Consider whether it should be awarded beamtime

Experiment title: The Placement of Saccharides in Lipid Bilayers

PI Surname: Garcia Sakai Instrument: NG1 REFL

Scientific Reviews

Reviewer1 Rating: F-P

The scientific case for this proposal is **very interesting**. It is an important issue in biology the understanding of the mechanisms by which sugars stabilize membranes. Users propose to look at the insertion of Sugar X in planar adsorbed single bilayers. **the feasibility of the experiment is not clear**. A simulation shown in figure 2, the region where differences appear in the system with h- and d- sugar has **very low reflectivity and differences are likely to be within the experimental error bars. It would have been useful to show the comparison with the bilayer alone but I suspect that the curve is very similar and difficult to determine. Maybe other partially labelled systems could help.**

Reviewer2 Rating: F

This proposal is an **excellent idea** but it only rates a fair use of neutron time because **background**. The creation of lipid layers is not trivial and the exposure of them to sugars could have unexpected consequences.

Reviewer3 Rating: G-F

The introduction of sugars into lipid bilayers is an **interesting fundamental** issue. The lipid system the team have chosen has been widely studied as a model system which has lead a large number of publications. However, **the approach the team have chosen with only using h- and d- sugar is not very different between the two models that have been proposed**. The difference in the calculated reflectivities of the two models is small and contrast variations will be key to disentangle the morphologies unambiguously. This will be true especially if something like a mixed mode occurs.

Reviewer4 Rating: E

The aim of this proposal is to investigate the interaction of sugar with a lipid bilayer, in order to gain insight into how the sugar interaction alters the phase behavior and structure of the lipid bilayer. This is a well defined problem in the mechanism of cryopreservation. **Neutron Reflectivity experiments will enable the authors to distinguish between the two models and biological significance in the area of biopreservation of membranes, and NR may be the best way to address this question** (the proposal is well described and supporting calculations of the expected reflectivity profiles) and should have a high success rate, and the proposal is well described and supporting calculations are already executed.

Reviewer5 Rating: E

In my view this is an **excellent idea** in the field of small molecules (sugars)-membrane interactions. Understanding the location of sugars in the model lipid membrane is of great importance. **Neutron scattering** (small angle or reflectometry) and wisely chosen contrast conditions. Access to the deuterated sugar would be of biggest importance. **This is well described and supporting calculations are already executed.**

Comments: Should have shown reflectivity for bare bilayer compared to bilayer with sugar. It is not clear what measurement sensitivity is required. Need to demonstrate feasibility.

Technical Review

Days Recommended: 6
Technically feasible.

Experiment title: Dynamics of phospholipid vesicles in the presence of bioprotectants
PI Surname: Garcia Sakai Instrument: NG5 NSE

Scientific Reviews

Reviewer1 Rating: G-F

This is a nice proposal with real biophysical relevance. Nevertheless it seems to me that addressing a dynamical issue with no exact information related to the detailed structure of the system is adventurous. A NSE experiment is therefore in my view still premature. The author should apply on SANS machines to first elucidate how the sugar interacts with the vesicles: few contrast matching experiment should reveal if the sugar can be described as a core-shell object or is a biphasic system etc etc. When structural data will be available, the author will have a very strong motivation to be strongly encouraged to apply again for NSE at that time.

Reviewer2 Rating: G

General problem of sugar bioprotecting effect which is not clearly understood. The author wants to study the presence of sugar X molecules and they want to extend to sugar Y and sugar Z. I don't understand how they can distinguish between the 3 hypothesis.

Reviewer3 Rating: VG

The proposer wishes to understand the characteristic interactions between sugar and lipid membranes. Comparing, otherwise, the same chemical formula) via investigating the membrane fluctuations in the presence of sugar. The study of the interaction of sugars with biomembranes is of interest due to the important biological role of sugars. The experiment may very well justify the use of the spin-echo technique, although the use of the Zimm-Bragg model is questionable. In any case, differences on the relaxation rates between membranes carrying the different sugars will be a good indicator of the sugar-lipid membrane interaction.

Reviewer4 Rating: VG

The modification of the bending modulus of lipid membranes by the addition of sugar X. The experiment seems to be promising in terms of interesting results since a lot of data on sugar X. The experiment seems to be promising in terms of

Technical Review

Days Recommended:

The proposer has measured the bending modulus of lipid membranes. The experiment is feasible. The estimation of the beam time in the description is 7 days although their requested number of days is 6. The experiment is feasible to complete the proposed experiment.

Final decision

Days Requested: 6.0

Days Alloc.: 0.0

Comments: The BTAC regrets that the very high demand for NSE makes allocation of beam time for this proposal impossible.

Experiment title: Residual stress mapping in Compact Tension (CT) test specimens with strain misfit remote from crack tip

PI Surname: Experimenter Instrument: ISIS ENGINEX

Scientific Review

Rating Poor

Comments: The panel found elements of this proposal rather puzzling. It was not clear why the proposed method was the most straightforward for introducing a different residual stress field rather than say, simply changing the geometry of the sample. Also, it was felt that the finite element model calculations should have been more detailed and presented along with the proposal. Some issues of feasibility were also identified. For example, the proposed loading of the sample along the vertical axes under a load would require a vertical loading system. The use of the 0.5mm collimators would likely lead to significant issues. If the issues identified above are addressed, in particular the issues with the proposed experiment is the best design.

Reviewer: Reviewer 1

Rating: VG (Very Good)

It is proposed to study the spin excitation spectrum of the new pyrochlore material Gd₂Pt₂O₇. The system is quite different from other Gd pyrochlores and the question of the role of exchange pathways involving Pt is well formed. Experiments on these materials are highly challenging on account of the exceptionally high absorption of Gd. They have for this reason fabricated samples which are very thin, but this produces only a small amount of sample. **They claim to have had success with a similar amount of material but this claim has no support is given and the paper is in preparation.** The experiment is worthwhile pending instrument time.

Reviewer: Reviewer 2

Rating: VG (Very Good)

The powder-averaged spin wave dispersion will be obtained from the Brillouin scattering data to be obtained in DCS will be essential to obtain such constants with the necessary accuracy to make the comparison with the theoretical calculations. I believe that the proposed experiment is interesting and the results will be relevant to the understanding of the magnetic properties of the material.

Reviewer: Reviewer 3

Rating: VG-G

The proposal is well motivated. In this class of materials, gadolinium-pyrochlore compounds and inelastic measurements of similar materials should provide more information to obtain J values and compare them with other materials in this class. The sample mass reported is sufficient for a successful experiment.
